SUBJECT: ELECTRON UPGRADE
FOR MCNP4B

Abstract:

The focus of this effort was the integration into MCNP* (ref. 1) of the ITS3.0(ref. 2) radiative and collisional stopping power (refs. 2 and 3) and bremsstrahlung production model (refs. 2, 4, 17, and 18). The integration was achieved with the development of a patch to MCNP4B and a new electron physics library database, el3w (like el1). SQA of the patch and database are still ongoing. However, improvements in the stopping power model and bremsstrahlung model are presented. Moreover, in the process of successfully achieving this goal several other related (bremsstrahlung angular distribution models) or otherwise unforeseen problems (electron step-size artifacts or thick target bremsstrahlung production problems) were identified and unfortunately not solved yet since they involve much more work. Several bugs have been found and eradicated.

Overview:

The memo is organized as follow:

- 0) Background
- 1) el3w database, the new database library
- 2) code modifications for new algorithms to use the new database and other enhancements
 - 2a) radiative stopping power
 - 2b) bremsstrahlung production
 - 2c) density effect
 - 2d) relaxation
 - 2e) variance reduction

*MCNP is a trademark of the Regents of the University of California, Los Alamos National Laboratory

- 2f) bug fixes
- 3) verification
- 3a) ITS stopping powers
- 3b) ITS cross section comparison
- 3c) Implications
- 4) preliminary validation based upon Gierga and Adams
- 4a) comparison with Faddegon for bremsstrahlung production
- 4b) depth dose in water
- 5) future work

Background:

In order to perform radiography analysis, accurate transport models are required to define the bremsstrahlung source and contamination in the object. Several authors (refs. 7 - 10, this is list is not meant to be exhaustive nor definitive) have examined the accuracy of various bremsstrahlung models in transport codes (MCNP¹, ITS² and EGS⁵). From these studies, possible deficiencies in MCNP were identified and sought to be corrected. As an example of the results found, figure 1

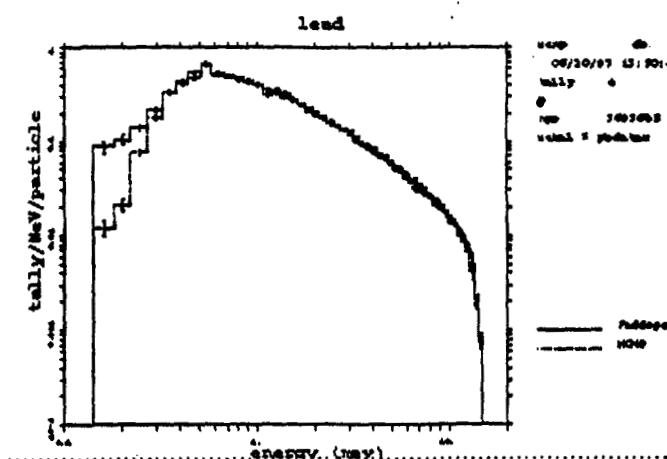

Figure 1: Bremsstrahlung Spectra for 15 MeV electrons on Lead.
Calculation (MCNP) and experiment (Faddegon)

displays the bremsstrahlung spectrum for 15 MeV electrons on lead calculated with MCNP4B and measured by Faddegon where spectral variations at low energies are present. Moreover, the electron physics package in MCNP is based mostly on ITS1.0 (ref. 6) physics with an upgrade to ITS3.0 physics for the calculation of energy loss straggling and calculation of the ionization potential. A more complete upgrade would be desired to include more of the ITS3.0 package and/or the database from ref. 11..

el3w database

The previous electron evaluation database was stored in library file, el1. Essentially, this file was a partial rewriting of the ITS1.0 xdata file into a format suitable for reading by MCNP (ACE format.) The initial few words of each data block for a particular Z were peculiar to MCNP but otherwise it just reformatted the data to be read by subroutine getxst for use in the subroutine xsgen with appropriate offsets. As far as I was able to determine there was no processing of the data only rewriting.

Following this philosophy, a code was written to extract and reformat the desired portions of xdata from ITS3.0 and generate the new library file el3w. The code for doing this reprocessing is presented in Appendix A and is available on cfs. The code represents an evolution of what the database needed from its progenitor and could still further evolve.

The following tables are the list of data pointers used in el3w and el1 and some explanation of their use. Table 1 lists the nxs array entries. These are mostly lengths of blocks of data. However, nxs(16) now has special meaning and is a flag for using the new its3.0 data and algorithms. Table 2 lists the jxs array. Finally, the crux of the puzzle is the contents of the exs array which is presented in Table 3.

Table 1: nxs array

nxs	exposition el3w	el1
1	length of XSS data set	length of XSS data set
2	z	z
3	number of radiation stopping power interpolation points	number of radiation stopping power interpolation points
4	number of mott scattering cross section corrections	number of mott scattering cross section corrections
5	number of electron energy points for bremsstrahlung interpolation	number of bremsstrahlung interpolation points

a. This explains the 2170 (2160+10) in getset for the electron offset.

Unfortunately, the electron side of MCNP has its own peculiar way of dealing with its cross section data and storing it. That is for neutrals all the transport data is stored in the XSS arrays and very few arrays are "hardwired" to reflect the physics manifest in the evaluation. (An example may be the RTC array which is hardwired to store only ten different cross section data.) Moreover, the XSS data persists after it has undergone the ordeal of expunging; the EXS data is overwritten since the relevant physics data has been processed and then stored in various arrays. As such, we have found that even though the electron portion of MCNP seems like an ideal candidate to become a "module", it has interspersed its memory management throughout the code.

The problem is simple, the physics data is stored in the database as a reduced set of data over a range where interpolation is valid while it is used in transport on a much finer or at least different scale. The original code had the size of the expanded or internally calculated arrays parameterized and the dynamic allocation of memory was done based on those parameters. For the new database, the parameterization has been retained but in such a way as to allow for regression compatibility. It is expected that this way of dealing with data structures will be amended in the future, so that the code can readily accept new data evaluations without being constrained to parameterizations based on different evaluations.

The parameters used in the electron databases are listed and explained in the following table.

parameters	exposition on parameter	e13w	e1
mtop*	number of ratio values of photon energy to electron energy for brems production	89	49
mwng*	number of ratio values of photon energy to electron energy for brems detailed brems angular distribution	(mtop+1)/2	(mtop+1)/2
mstp*	coarsening factor for electron energy grid for detailed brems angular distribution	actually 34 is used; to be replaced by nxs(16)	actually 25
mpng	number of photon angular bins	21	21
mbng	number of possible photon to electron ratio values from the its3.0	51	unused

* These parameters have corresponding variables, ntop, nwng, nstp respectively, to toggle between databases.

Code and Algorithm Modifications

The patch to achieve these changes is presented in Appendix B.

2a) Radiative stopping power.

The ITS3.0 database has a more recent evaluation of the radiative stopping power. To use the evaluation in the code required a few small changes since the effect of electron bremsstrahlung has been included in the database. The stopping power is

$$\frac{dE}{dx} = (Z + \eta)\Phi_{rad}$$

The database originally contained a table of energy and Φ_{rad} with the assumed value of unity for the electron bremsstrahlung contribution, η . The new evaluation includes a newer table of energy and Φ_{rad} as well as η .

2b) Bremsstrahlung production

The brems production database has been extended to cover a larger range of photon energies. The photon energy from a bremsstrahlung event is specified in terms of a ratio of the incident electron; the range of ratio values is from one to 10^{-6} for the el3w database while the el1 range was from 0.9999 to 10^{-3} . The following table gives the ratio values for both databases.

el1:

rkt=.001,.00125,.0015,.00175,.002,.0025,.003,.0035,.004,

0.003,0.0035,0.004,0.0045,0.005,0.0055,0.006,0.007,0.008,
0.009,0.01,0.0125,0.015,0.0175,0.02,0.025,0.03,0.035,0.04,
0.045,0.05,0.055,0.06,0.07,0.08,0.09,0.1,0.125,0.15,0.175,0.2,
0.225,0.25,0.275,0.3,0.325,0.35,0.375,0.4,0.425,0.45,0.475,
0.5,0.525,0.55,0.575,0.6,0.65,0.7,0.75,0.8,0.85,0.9,0.95,0.97,
0.99,0.995,0.9995,1.0

The production of bremsstrahlung from an electron of energy, E, is determined by numerical or analytic integration of the cross section over the above specified ranges of photon

energy ratios. Chosing the best cross section for all energies is non-trivial and has evolved over the years*. For the el1 database, most of the production cross sections are derived from Koch and Motz (ref. 15 and refered to as K&M hereafter) with some exceptions near the "tip" (the "tip" is the photon phase space near where the photon is extremely forward peaked and has nearly all the incident electron energy.) Berger and Seltzer (ref. 16) describe their best evaluation of which cross sections should be used over various energy ranges. The el1 database follows that evaluation except for not using the Schiff formula (see ref. 15 for formula).

In the el3w evaluation or database, the production cross section for bremsstrahlung photons and energy spectra are from the evaluation by Seltzer and Berger (refs. 2, 17, 18 and refered to as S&B collectively hereafter). We summarize the salient features of the evaluation below; more details can be found in the evaluators' documentation. The evaluation uses detailed calculations of the electron-nucleus bremsstrahlung cross section for electrons with energies below 2 MeV and above 50 MeV. The evaluation below 2 MeV uses the results of Pratt, Tseng, and collaborators, based on numerical phase-shift calculations (refs. 22, 19, and 20). For 50 MeV and above, the analytical theory of Davies, Bethe, Maximov, and Olsen, (DBMO ref. 23) is used and is supplemented by the Elwert Coulomb (ref. 26) correction factor and the theory of the high-frequency limit or tip region given by Jabbur and Pratt (ref. 27). Screening effects are accounted for by the use of Hartree-Fock atomic form factors (ref. 25). The values between these firmly grounded theoretical limits are found by a cubic-spline interpolation as described in refs. 64 and S2. Seltzer reports good agreement between interpolated values and those calculated by Tseng and Pratt (ref. 21) for 5 and 10 MeV electrons in aluminum and uranium. Electron-electron bremsstrahlung is also included in the cross section evaluation based on the theory of Haug (ref. 24) with screening corrections derived from Hartree-Fock incoherent scattering factors (ref. 25). The energy spectra for the bremsstrahlung photons are provided in the evaluation. Finally, the comparisons with experiments presented in S&B indicate the validity of their approach**.

In summary, then, the calculation of the production cross section for bremsstrahlung is given by numerical integration of various formula which reflect the best evaluation at the time of the bremsstrahlung process. For el1, this integration is done in the code and most of the formula are related back to the review of K&M, while for el3w, the integration and any corrections are done in the evaluation. Consequently, all of subroutine brem had to be rewritten for the evaluation of the bremsstrahlung cross section, pbr, spectra, eba for el3w. The new algorithms for the el3w database are derived from the ITS code which presumably reflect those authors' recommended interpolation schemes and have been incorporated in brem since the pbr and eba arrays are used for the calculation of thick target brems.

*We quote from Seltzer and Berger, "Many theories of the bremsstrahlung process have been developed, each with its own approximations, limitations and regions of applicability. To obtain accurate cross sections over a wide range of conditions, it is necessary to combine, and to interpolate between, the results of several theories."

**The validation problems discussed later will eventually be augmented to include this set.

The detailed angular distribution calculation has been modified only in so far as the resolution of the energy grids has been more refined. For el1, the angular distribution was

calculated for electrons with energies $E_n = \frac{E_{max}}{2^n}$ with n being a positive integer. (Recall that

electron transport parameters are calculated on an energy grid with $E_n = \frac{E_{max}}{2^{n/8}}$.) For el3w,

$E_n = \frac{E_{max}}{2^{n/2}}$. Moreover, for el1 the photon ratios used every other ratio value in the production

evaluation. For el3w, the ratios are read from the database and are fewer than every other. (Presumably every other could be used for el3w or even every one. However, this is what ITS does.) The angular distribution is determined by numerical integration of several formulas from K&M using these electron energy values and photon energy ratios. Consequently, the modifications to subroutine brang have been minimal. As a passing note, it is not apparent that 2BS is used in the angular distribution calculation in brang though one may have expected it to be used from ref. 16. It might be speculated that this may account for some of the differences seen between EGS and MCNP.

In MCNP, brems production is sampled along an electron substep. The probability of an event(s) occurring in a distance δ is $1 - e^{-\Sigma_{brem}\delta}$, with the number of events being sampled from a Poisson distribution. If the probability of an event occurring is small, then only the first non-zero term in the Taylor expansion of the probability is kept and used to sample if one and only one event has occurred. This is the procedure used in MCNP for el1. For el3w, the sampling has been modified to sample from the Poisson distribution so that zero, one or more events could occur, though two or more are extremely infrequent. The electron's energy is decremented after each event and used to scale the energy of the photon from the next event. This procedure is consistent with the method employed by ITS3.0.

2c) Density Effect Correction

The stopping power has a correction term to account for the polarization of the media through which the charged particle passes. Sternheimer, Berger and Seltzer (ref. 14 and referred to as SBS) have given a method to calculate the density correction in ref. sbs in terms of the plasma frequency of the media, the oscillator strengths and occupation numbers given by Carlsson (ref. 28), and the ionization potential of the media. The method finds an adjustment factor, ρ , which

gives the ionization potential for the media at the specified density from their eq. (10) where I is

$$\ln I = \sum_{i=1}^{n-1} f_i \ln \left[(hv_i\rho) + \frac{2}{3} f_i (hv_p)^2 \right]^{1/2} + f_n \ln (hv_p f_n^{1/2})$$

the ionization potential of the medium (consistent with the prescriptions of ref. 10), h is Planck's constant, f_i is the fraction of electrons at that level, v_i is the oscillator frequency of that level, v_p is

the plasma frequency of the medium ($v_p = \left(\frac{ne^2}{\pi m_e} \right)^{1/2}$) and n is the number density of electrons in

the medium). The adjustment factor is found in subroutine den1 using a newton search method; for high density materials the newton search method may fail and the code will issue a warning and nullify the density effect correction; this is consistent with the fundamental theory of the density effect. Once the parameter has been found, it is used in subroutine den2 to calculate the density effect correction as specified by Eq. (5) in sbs.

$$\delta(\beta) = \sum_{i=1}^n f_i \ln \left[\frac{l_i^2 + \beta^2}{l_i^2} \right] - l^2(1 - \beta^2)$$

where $l_i^2 = \left(\frac{2}{3} f_i + \left\{ \frac{v_i \rho}{v_p} \right\}^2 \right)$ and for conductors the nth level has, $l_n^2 = f_n$ and the parameter, l, is the solution of eq. (6) of sbs.

$$\frac{1}{\beta^2} - 1 = \sum_{i=1}^n \frac{f_i}{l_i^2 + \{(v_i \rho) / v_p\}^2}$$

Previously, MCNP used the published empirical fit formula of Sternheimer and Peierls (ref. 15). The method described in sbs is an improvement upon the sp fit formula as discussed in sbs.

For the sbs treatment, the conduction state of the material is needed which is specified with cond=0 for a non-conductor, and cond=1 for a conductor; any non-conducting isotopes in a conductor are handled as non-conductors. The user can specify this on the m card with the keyword cond. The code will provide defaults which the user can override for the specification of a non-conductor with cond=-1 on the m card. The scheme is:

initially - cond=0 (non-conductor)

in range -

check if all isotopes are conductors and set cond=1 if cond=0

check that there is at least one conducting isotope is present if cond=1, if not set cond=0

if cond=-1 override any prior decision on the conduction state and make non-conductor cond=0.

The density effect calculation has a problem for materials of a single element or Z but specified with multiple isotopes or ZAIDs. This is traced to the implementation of Eq. (10) of sbs and the ionization sum rule of ICRU 37 (ref. 10). ITS has changed that implementation slightly. Making it consistent with the above rules and such that the same answer is obtained regardless of isotopic specification worsens the verification discussed later. We note this as a problem.

2d) Relaxation

Relaxation has been a problem in MCNP. There are two algorithmic branches for an atom to relax after undergoing an ionizing event depending upon the source of the ionizing event. If the source of the ionization was a photon the atom's relaxation will be described using the model of Carter and Cashwell (ref. 29) where the major K and L line photons may be emitted or an Auger electron with energy exs(jxs(1)) which has been stored in eek for that material. If the source of ionization was an electron then if the atom fluoresces the photon will have only an average K energy given by eek; Auger transitions are treated the same. Under many circumstances, these approximations would not be too conflicting. However, there is an inconsistency, that fluorescent radiation will be emitted with different lines. To remedy the inconsistency, relaxation from an ionizing event has been combined into a single subroutine, flaug, called by either colidp or kxray as needed. Most of flaug is similar to the relaxation code in colidp except for mostly bookkeeping changes needed to accommodate calls from kxray. The only other physics change needed in flaug for a call from kxray is that the atom is required to relax either through an Auger transition or fluorescence; for a photoionization the atom is not required to Auger or fluor (presumably it relaxes through lower energy transitions neglected in our models.) The arguments of flaug are the energy of the ionizing quanta, the photon energy for a photoionization or max K shell energy, edg*1.0001 (1.0001 prevents any round-off problems), the isotope undergoing the interaction (the highest Z isotope for kxray), the material identifier, and a flag for electron or photon ionization event.

Since, eek is not used any longer as the energy given to either a kxray fluor photon or Auger electron, its value has been lowered to the more probable value (used in the POEM code of

ref. 30 and derived by inspection from ref. 31) of $E_A = E_{\bar{K}} - 2E_{\bar{L}}$ as compared to the previous value of $E_A = E_{\bar{K}}$ and is used only to give the value of Auger transition electron.

This model is still quite crude and approximate though no longer inconsistent. Further improvements will be discussed later.

2e) Variance reduction

The variance reduction discussed in this section pertains to brems production only. There are two vr techniques for brems production:

1) bbrem

Bias the brems photons produced toward higher energies.

2) bnum

Produce bnum more photons.

For el3w, the format of the bbrem card has not been changed to allow for backwards compatibility. The entries on the bbrem card are mtop_el1=49 biasing numbers for the production of photons followed by cell numbers where the biasing will be applied. For el3w, the number of relative photon energy bins is larger so to allow compatibility with the previous bbrem card, the biasing probabilities over the low energy photon bins from the card are linearly interpolated over the low energy bins in el3w.

In MCNP, when bnum was invoked on the phys:e card, bnum identical photons were generated from a brems event with wgt=wgt/bnum. For photon thin problems, such a biasing scheme is not effective and for thick problems, it may be of only marginal help. The more common method (refs. 32 and 2) is to sample the production distribution bnum times using the same reduced weight for each photon. The sampling is done in a do loop bnum times over the full Poisson sampling of events. Note for bnum<1, the sampling of energy loss is done once but photons may or may not be produced based on bnum+rang() being zero or one. The sampling of several different photons with reduced weights has been shown to be more effective in photon thin problems (Gierga and Adams). There is a question as to how to deal with the energy loss from the more numerous and different pseudo events. For bnum>0, the first sampling of the photon(s) energy is used to calculate the energy loss. For bnum<0, the average of all photons produced is used to calculate the energy loss. The first method does not conserve energy, but more properly gives the straggling contribution of radiative energy loss. The second method more nearly

conserves energy and gives the CSDA energy loss more closely at the expense of the straggling. The latter method was the one used by Gierga and Adams in their report.

Finally, for any bnum scheme to be effective the number of secondary electrons generated must be controlled; secondary electrons take up most of the time in transport calculations. Controlling the number of secondary electrons generated is done with the enum entry on the phys:e card. The default has been one regardless of the value on the bnum card. This has been changed to scale the production down by the inverse of the number of photons produced; enum=1/bnum. The user can override this default setting.

Another vr scheme suggested by R. A. Forster is to have a brems occur on each substep. This scheme is done when the tenth entry, numb, on the phys:e card is non-zero. On each substep only one photon is produced with weight equal to the probability of an interaction on that substep. If this was a real interaction, then the energy loss is calculated and applied to the electron. The subsequent photons generated in the Poisson sampling are given the nominal, unreduced weight. In this scheme, enum is arbitrarily set to 1%.

2f) Bug fixes

The primary bug has to do with how the electron (charged particle) algorithms handle materials described with isotopic decomposition. The ionization potential has a factor of 1.13 applied to it when the material is a mixture of different elements. However, a pure material, i.e. composed of one type of atom, may be described with its isotopic decomposition and erroneously have the factor of 1.13 applied to the potential. To correct this each isotope is checked to see if its Z is different, if not the factor of 1.13 is not applied. Clearly, more work needs to be done here, since trace elements may be included which should not effect the ionization potential.

This isotopic decompostion bug also appears in the new density effect calculation. The fit parameter calculated from Eq. (10) of sbs is different for single zaid and composite zaid materials. This is because when Eq. (10) is calculated in den1 it uses a different elemental weighting scheme than used for the calculation of the ionization potential. Since we obtain excellent agreement with ITS on materials, we note this discrepancy; it is usually an error of 0.1%, though can be larger.

Another related bug is in the determination of the kxray production probability. The atom fraction of the first highest Z isotope is used. If several isotopes of the same Z were present, then the probability is too low. This has been corrected to use the sum of the atom fractions of all the highest Z isotopes

Turning off kxray production was not done when xnum=0 on the phys:e card. The test has been changed from ".gt." to ".ge." in subroutine xsgen. Moreover, there appears to be a special treatment for xnum<0 where the probability, d, of kxray production for an electron is calculated for the electron till it has gone below cutoff. This would be the probability of kxray production over the full electron range. For xnum<0 the probability is scaled by |xnum|/d. This treatment of biasing raises a point of discussion related back to the bnum treatment.

3) Verification

There exist no analytic problems against which to verify the correctness of the physics or variance reduction models implemented in the code. However, since the database for stopping powers and bremsstrahlung cross sections has been adapted from an existing code system, ITS3.0, verifying the correctness of the implementation will be obtained by comparing to that code system.

3a) Stopping powers

Stopping powers are calculated and printed in the MCNP print table 85 and in the output from ITS code xgenp. Relative differences in ionizing and radiative stopping powers normalized to the ITS values for Z=1 to 92 over the energy range of 1 keV to 1 GeV are presented

in Fig. 2 (ionizing), Fig. 3 (density effect), Fig. 4(radiative). Generally, the agreement is to four

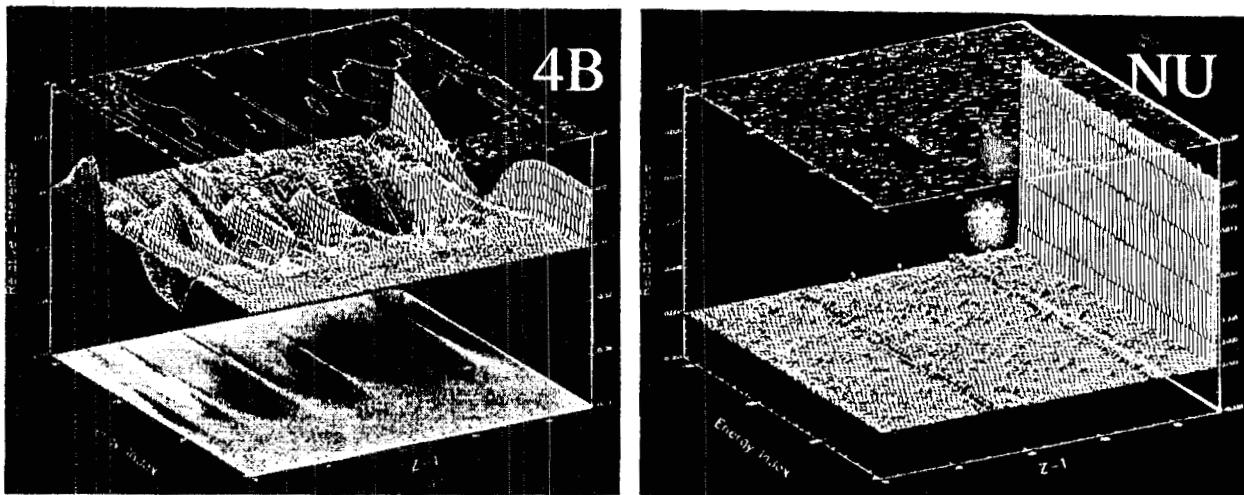

Figure 2: Relative differences between ionizing stopping powers from ITS3.0 and MCNP4B (4B) and ITS3.0 and MCNP4BNU (NU) all normalized to ITS3.0 for Z=1 to 92 from 1 keV to 1 GeV.

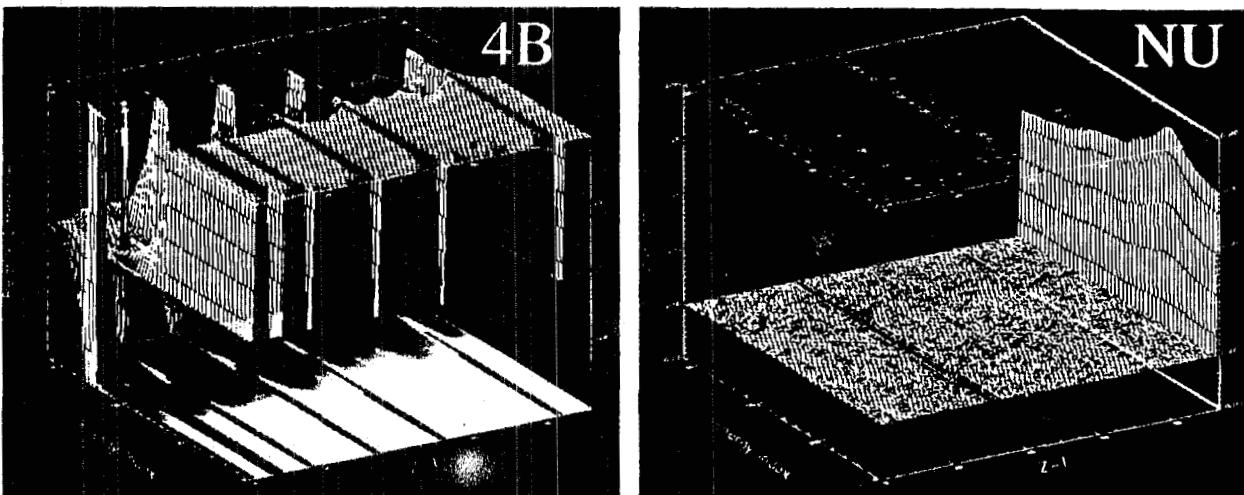

Figure 3: Relative differences between density effect corrections from ITS3.0 and MCNP4B (4B) and ITS3.0 and MCNP4BNU (NU) all normalized to ITS3.0 for Z=1 to 92 from 1 keV to 1 GeV.

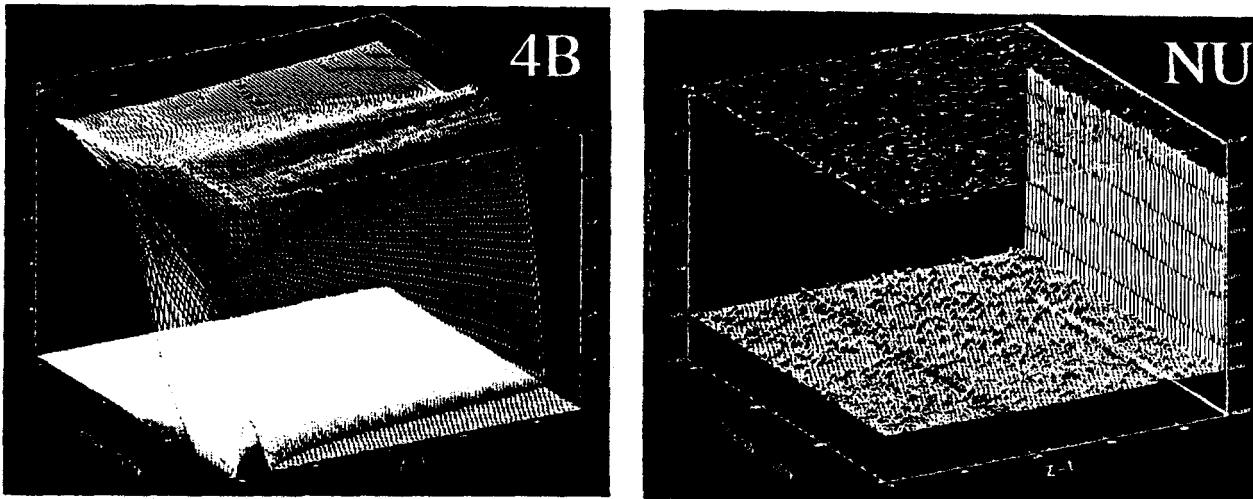

Figure 4: Relative differences between radiative stopping powers from ITS3.0 and MCNP4B (4B) and ITS3.0 and MCNP4BNU (NU) all normalized to ITS3.0 for Z=1 to 92 from 1 keV to 1 GeV.

significant figures and this level of agreement is satisfactory since the fundamental constants and atomic weights in ITS are slightly different from those in MCNP. The only problem material is Pu where the ITS atomic weight is significantly different than MCNP (and most standard tables.) Changing the atomic weight and modifying the constants in MCNP cause the stopping powers to be in agreement to four significant figures.

The stopping powers for materials was also verified. Using the materials of ICRU 37 and a few extra to span composites of a wide range of Z's, the same comparisons were done.

Figure 5 shows the comparison of the collisional or ionizing stopping powers. Figure 6 shows the

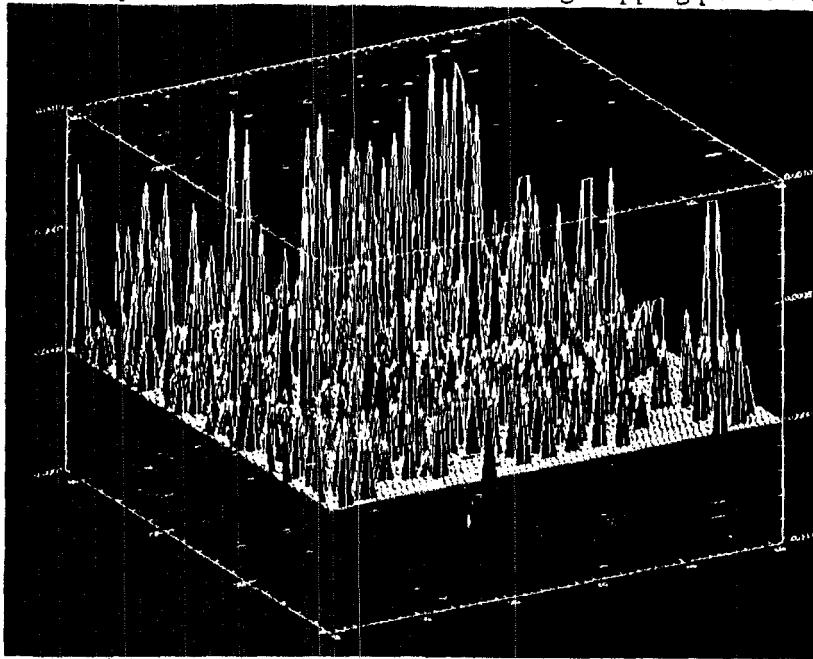

Figure 5: Relative differences between ionizing stopping powers from ITS3.0 and MCNP4BNU all normalized to ITS3.0 for a wide range of materials from 1 keV to 1 GeV.

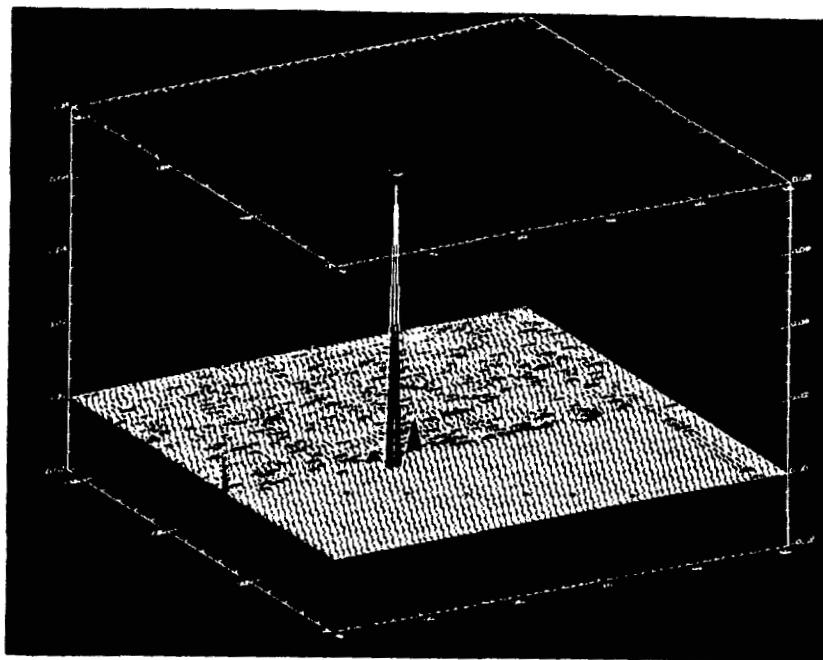

Figure 6: Relative differences between density effect from ITS3.0 and MCNP4BNU all normalized to ITS3.0 for a wide range of materials from 1 keV to 1 GeV.

density effect correction comparison and Figure 7 shows the radiative stopping power

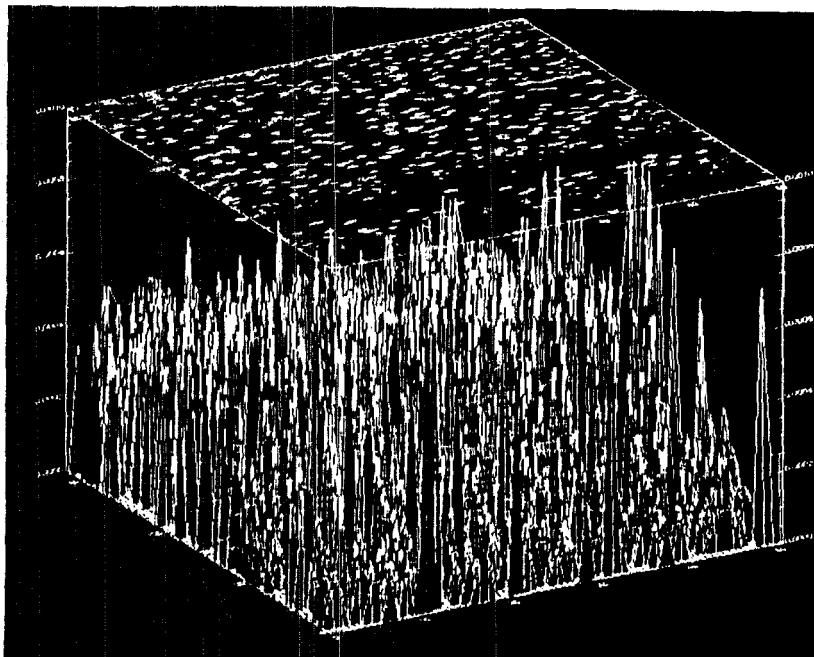

Figure 7: Relative differences between radiative stopping powers from ITS3.0 and MCNP4BNU all normalized to ITS3.0 for a wide range of materials from 1 keV to 1 GeV.

comparison. Once again the results are all within four significant figures except for a spike in the density effect calculation. This spike was for a very small correction which was near zero for both codes and so does not represent any significant problem.

In the patch, the bremsstrahlung production cross section array, pbr, the energy spectrum array, eba, and detailed angular distribution array, ech, are printed to separate files for debugging and verification purposes. H. G. Hughes maintains a version of the ITS3.0 code system where these arrays are printed to output files from the ITS3.0 cross section generating code xgenp. For all the elements for $Z=1$ to 92 and over the energy range of 1 keV to 1 GeV, the average relative error in the "pbr" array is 10^{-6} , in the spectra, 10^{-6} , and in the angular distribution array, 10^{-6} . The maximum for pbr is 10^{-5} . For the "eba" array, the maximum relative difference is 10^{-4} and is in the first bin which is typically a small number. For ech the maximum relative difference is 10^{-2} again for the same reason as for eba. Since the ITS3.0 code has changed the angular distribution calculation only (correctly), we have not changed our routine yet. Though it is recommended that these changes be made when the angular distributions are revised since the coding is more readable and easily related back to fundamental equations. Such revisions would make the inclusion of 2BS in the sampling scheme more straightforward.

The patch also uses an adapted cubic spline fitting routine in correspondence with ITS3.0. The sampling algorithms are in agreement except for the sampling of the angular

distribution. The patch includes what is needed to obtain exact ITS agreement though either method is valid.

The el3w bremsstrahlung cross sections stored in the pbr array are displayed in figure 8. The same array for el1 is also shown in figure 8. The curves are significantly different. Part of

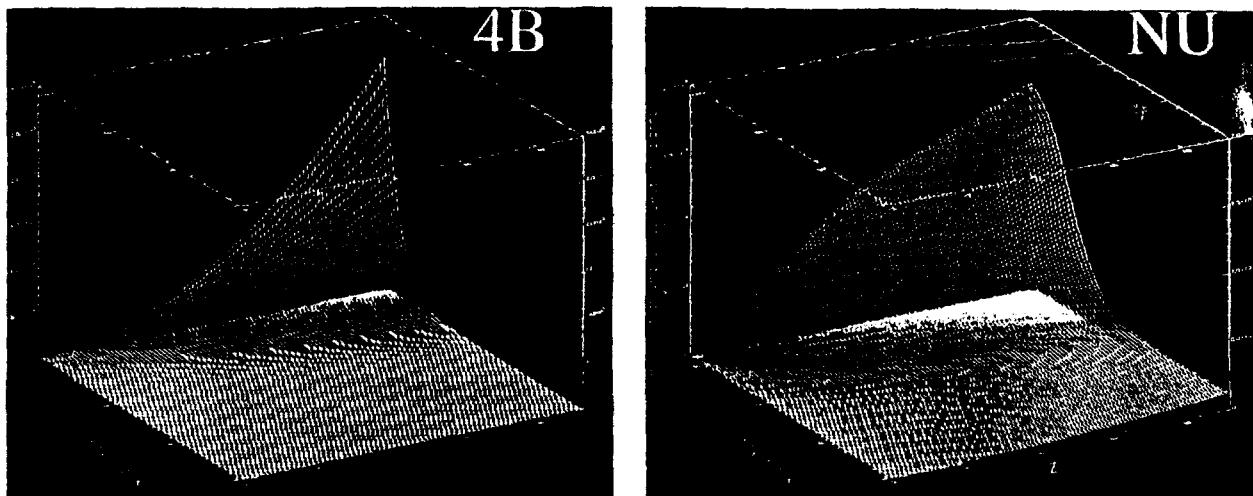

Figure 8: Bremsstrahlung production cross sections (pbr array) from MCNP4B (4B) and MCNP4BNU (NU) for Z=1 to 92 from 1 keV to 1 GeV.

the difference, as noted above, is that the el3w database and the el1 database have different lower limits of the photon energy for which the cross section was calculated. Symbolically, pbr for an electron of kinetic energy, T, is given by the following equation where the minimum photon energy

$$pbr(T) = \int_{k_{min}}^T \frac{d\sigma}{dk} dk$$

is kmin. Moreover, knowing that the eba array is the cumulative probability of producing a photon with energy between k/T and kmin/T, a scaling relation between the pbr arrays of the two databases would be

$$pbr_{el1}(T) = pbr_{el3w}(T)(1 - eba(0.001))$$

where $eba(0.001)$ is the value of the eba at that ratio. Thus a fairer comparison is between a scaled pbr for el3w and el1. Figure 9 shows the relative difference between the scaled el3w and

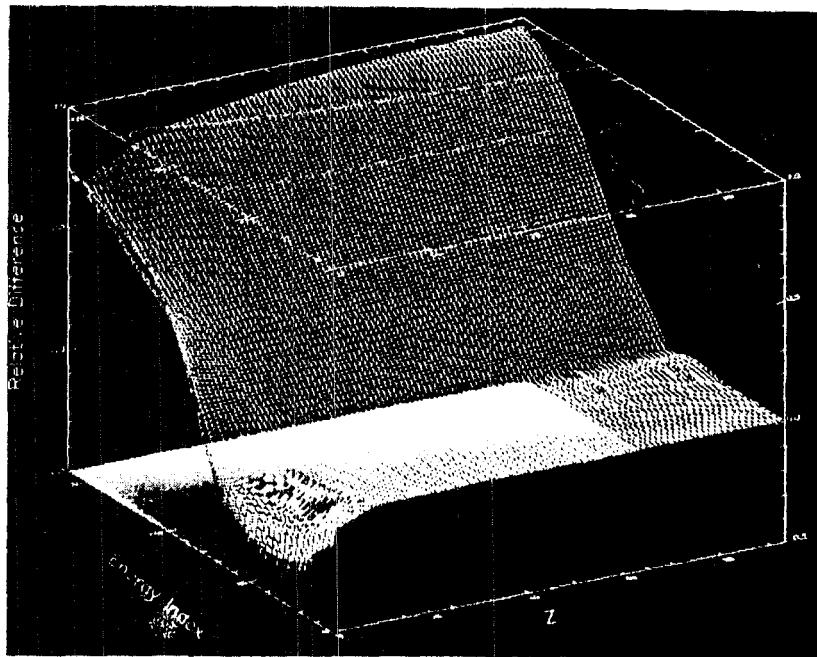

Figure 9: Scaled Bremsstrahlung production cross section relative differences between MCNP4B and MCNP4BNU for $Z=1$ to 92 from 1 keV to 1 GeV normalized to MCNP4B.

el1 normalized to el1. For low energies the differences are quite large and show that el1 had a very large low energy electron bremsstrahlung cross section.

At this level the algorithms for stopping power calculation and the bremsstrahlung production cross sections have been verified for all the elements and many representative materials over the energy range of 1 keV to 1 GeV. This level of verification meets or exceeds the verification standard of el1 and MCNP4A.

Implications:

Several problems have been suggested that show that the el1 model needed to be updated. Some of the problems still persist, however, improvements have been made. We have considered three energy ranges of problems for geometries similar to nominal converter foils.

The first is a low energy problem suggested by Newton Scientific. 20 keV electrons are normally incident on a 0.001cm W foil. The bremsstrahlung spectrum is tallied. Figure 10

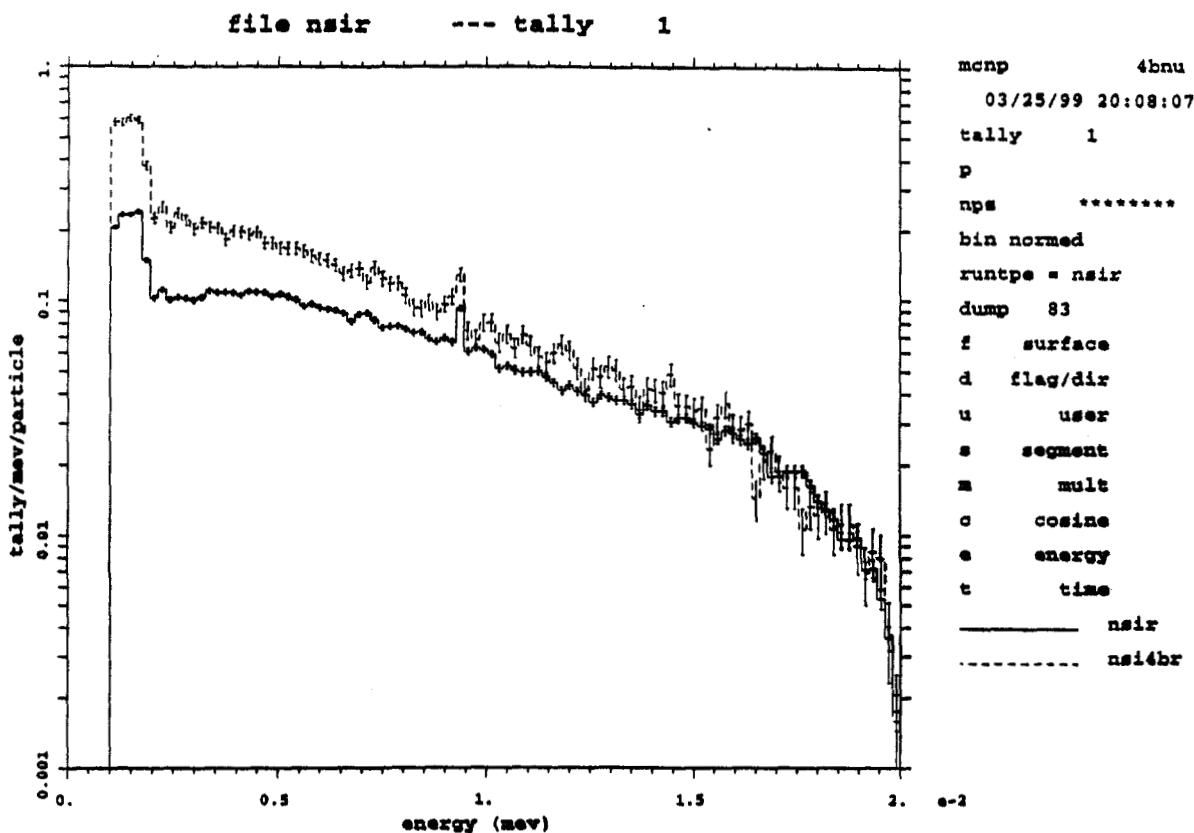

Figure 10: Bremsstrahlung spectra for 20 keV electron incident on 0.001 cm of W calculated with MCNP4B (nsi4br) and MCNP4BNU (nsir).

shows the spectrum calculated with 4bnu (the patched 4b which passed all the MCNP test problems) for the el1(4b in the plots) and el3w (4bnu in the plots) databases. The differences are quite large. In fact the 4b appears to have the M lines which of course it cannot. The 4bnu result is much less intense and more consistent with the NSI ITS calculation.

Higher in energy J. V. Siebers proposed a simple machine head model of a W/Cu slab. 6 MeV electrons are normally incident. He has noted that the bremsstrahlung yield downstream depends on the maximum energy of the spectrum. We have not addressed that problem yet but note that it also apparent in the ITS codes. Table JV shows the results of a calculation for that problem with two choices of EMAX (the first entry on the phys:e card). The total bremsstrahlung generated from the summary tables shows a 0.12% difference which is beyond the statistical bounds one would expect. The tally which scores the forward yield about a 1m from the converter

packs show a much larger variation. Even 4bnu has not answered this problem, however we do see that the yield is more forward directed by about 1%. Another implication apparent in this problem is inconsistency of the relaxation spectra as seen in Figure 11 where 4bnu has removed

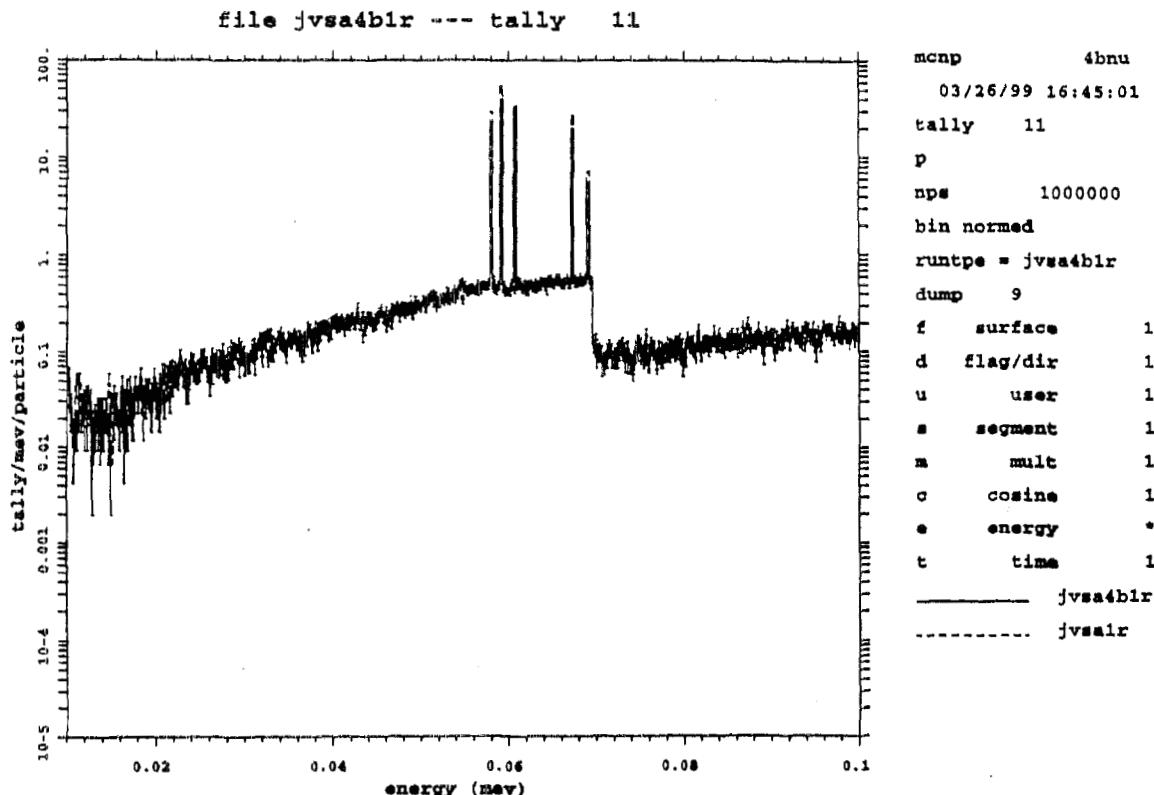

Figure 11: Bremsstrahlung and line spectra calculated with MCNP4B (jvs4bir) and MCNP4BNU (jvsair). The anomalous line has been removed in the el3w/4BNU calculation.

the anomalous line at 60.69 keV.

code	EMAX=100		EMAX=6	
mcnp4b				
bremssstrahlung	41622998	4.1623E+00	41551441	4.1551E+00
tally in forward cone	5.29151E-02	0.0014	5.15433E-02	0.0014
mcnp4bnu				
bremssstrahlung	41362833	4.1363E+00	41283862	4.1284E+00
tally in forward cone	5.35427E-02	0.0014	5.21917E-02	0.0014

Finally, at high energies, A. E. Schah von Wittenau suggested a typical converter foil 0.1 cm of W with 85.0 MeV electrons normally incident. The spectra calculated with the two different databases are presented in Fig. 12. The el3w (not labeled asvw4br) results are all

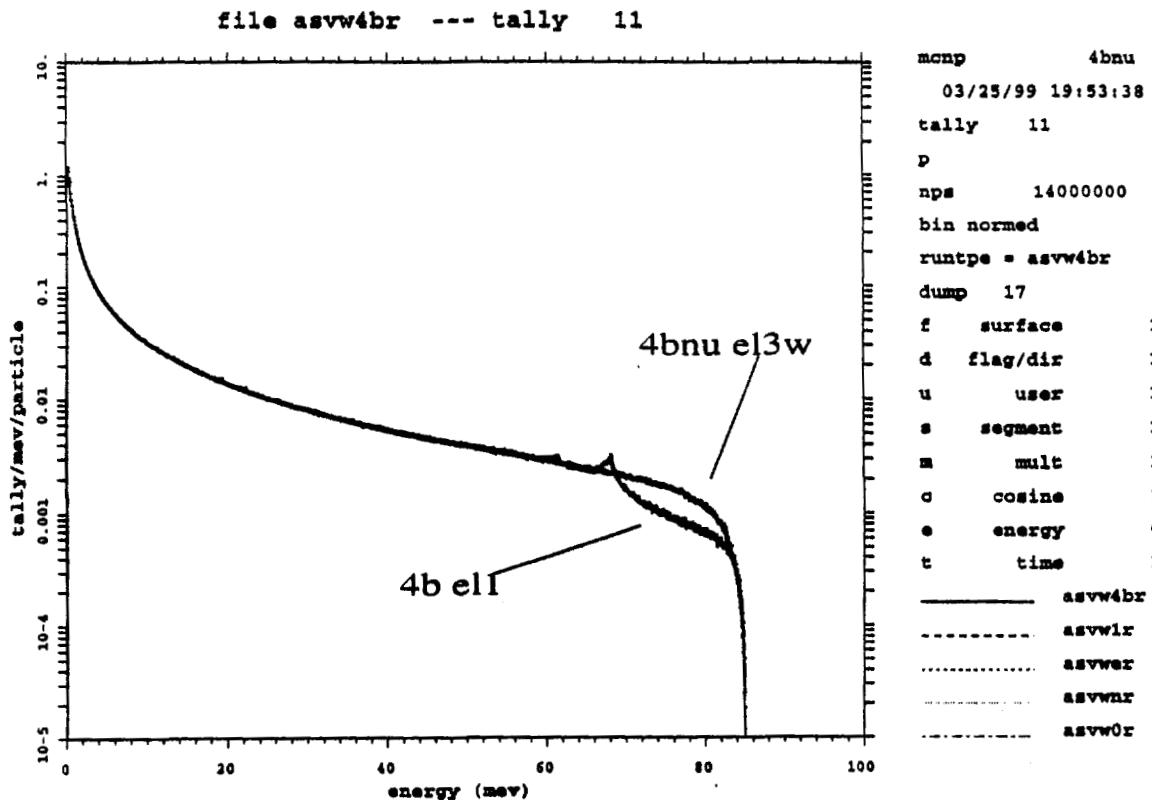

Figure 12: Bremsstrahlung spectra calculated with MCNP4B (asvw4br) and MCNP4BNu (others) for 85 MeV electrons incident on 0.1 cm W. Various variance reduction methods were tested giving nominally the same results.

smoother than the el1. The notches in the 4b calculation are probably due to non-smooth model transitions; 4bnu by definition is immune to such artifacts. All these problems except for asvw0 were run with some variance reduction. asvw1 has the new bnum biasing, asvwe is the same except W is made of its isotopic constituents, asvwn uses the numb biasing, asvw4b uses the old

bnum scheme. Fig 13 shows the spectra calculated with bbrem being used for asvw1 (labeled

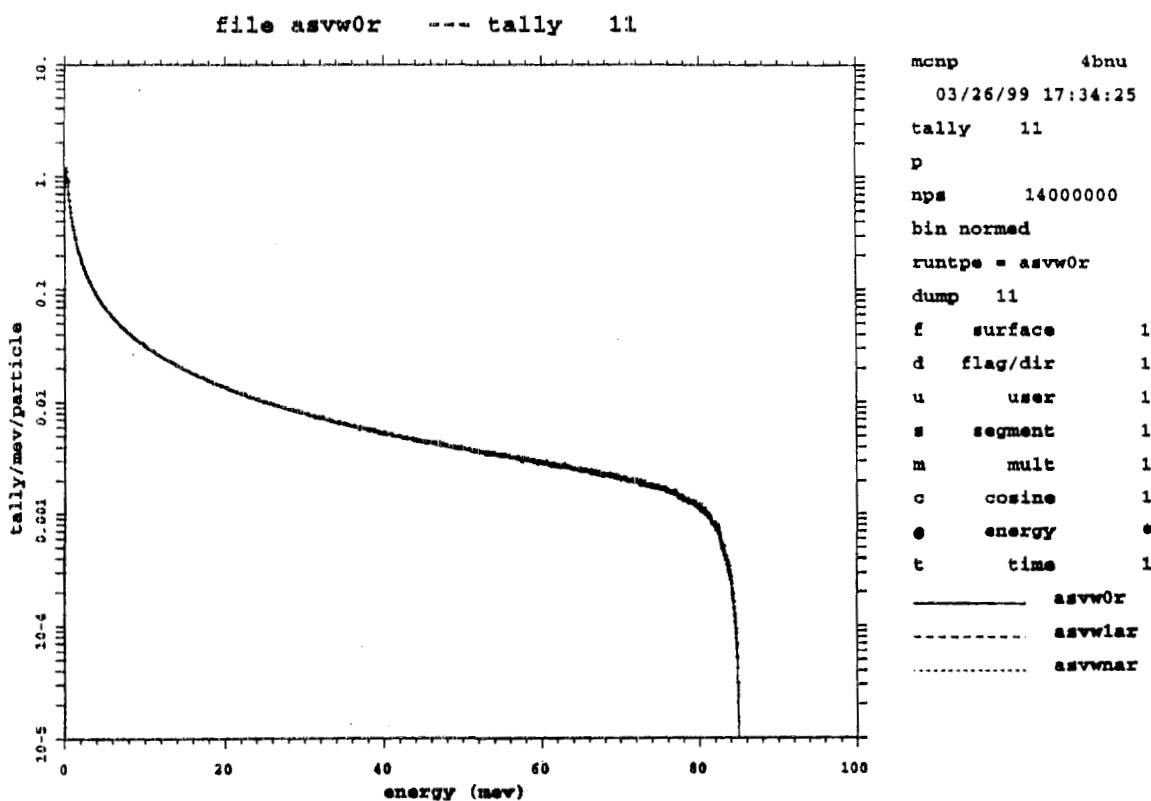

Figure 13: Bremsstrahlung spectra calculated with MCNP4BNU for 85 MeV electrons incident on 0.1 cm W with no variance reduction (asvw0r) and bbrem used in conjunction with new bnum biasins (asvw1ar) and numb biasing (asvw1nar).

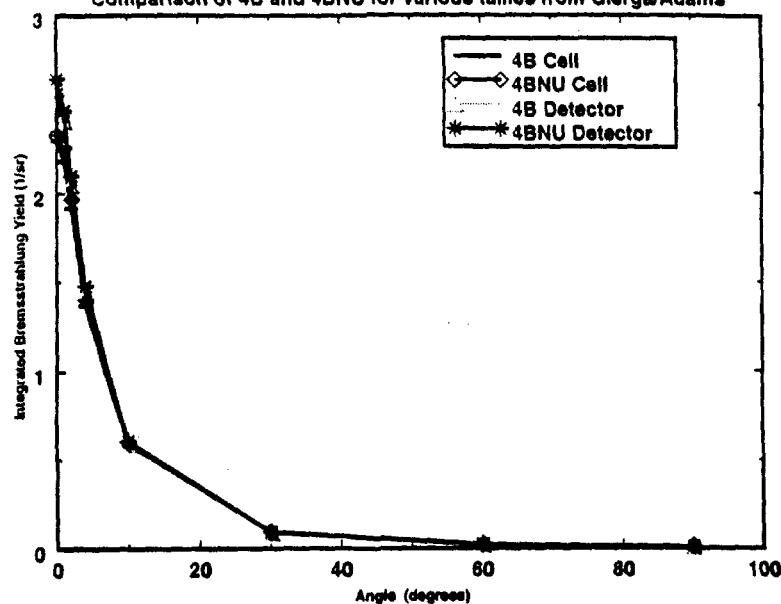

asvw1a) and asvwn (labeled asvwna) and asvw0. The impact of bbrem biasing has introduced no artifacts when used in conjunction with other biasing. It is amusing to note on this particularly thin problem, the largest form was for no biasing.

Validation:

Gierga/Adams provided a very large suite of validation calculation templates. Due to budgetary limitations this set was not expanded. Nor have all the templates been run, only a few of the bremsstrahlung sensitive ones have been exercised. The results follow. Appendix C presents tables of some of the plots for more detailed comparisons.

Testing:

To facilitate merging this patch with the evolving MCNP4C, several test problems have been generated. They fall into two classes. One set are the ones derived from the previous 4B test suite which were selected if they used the e11 database. This set consists of problems 04, 08, 10, 11, 20, 21, 22, 23, and 29. For problems 23 and 29, longer runs were done to assure that the test problems were giving reasonably assured results. A variant of 08 is included to assure that the code crashes and fails to run for mixed databases; this should not be allowed to be overcome with a fatal option since the results will probably be gibberish.

The second set focus on the new features mentioned above and are derived from the relatively straightforward "implication" validation set. inp30 and inp31 are derived from the high energy set. inp30 assures that the new bnum sampling is being done as expected with the bbrem card. inp31 checks the numb option for brems vr. inp32 is derived from the low energy problem with just fewer histories being run. It assures that the low energy portions of the database are being used as expected.

These test problems have exercised by D. Court and myself. Needless to say there are platform dependencies, however the test problems are easily checked with the converged results generated on Openblue.

Future work and conclusions:

The patch and database provide an improvement in the physics modelling of electron transport in MCNP. Comparisons with the progenitor code shows excellent agreement with calculated or derived quantities. Improvements in performance were illustrated with three sample problems. Comparisons with validation runs show improvement, albeit on the 1% level (as one might say the orginal developers did very good work so it is hard to improve it.) Several lessons have been learned from this effort on how new databases should be merged with the code. As such the original electron patch was a bandage and the current patch retains several of the "bandage" features.

There are still many remaining issues to be addressed for the electron/photon transport capabilities of MCNP.

- 1) The relaxation models are out of date and need to be improved (ref. 30 and 33).
- 2) Other bremsstrahlung and electron interaction databases (ref. 11) and the bremsstrahlung angular distribution calculation still is open
- 3) Emax and step size problems
- 4) Cleaning up the code and allow different databases to be used like the neutron side.
- 5) No-scatter calculation which is highly platform dependent.
- 6) Goudsmit-Saunderson treatment and general questions about multiple scattering and transport corrections such as TLC (transverse longitudinal correction).

7) Thick target bremsstrahlung.

Acknowledgements:

J. V. Siebers for helping debug the SGI version of the patch and suggesting the mid range problem. A. Schah von Wittenau. for suggesting the high energy problem and illuminating discussions on the bnum biasing schemes.

Patches to MCNP for the electron upgrade

Patch to 4xu with variables being defined at the being of patchf:

```
c      <<<< makemcnp changes for MCNP4B2 >>>>      loddat 09/22/97
c
c      For each fix, enter five integer parameters on one line in free
c      format, ip(1)-ip(5) described below, followed by the appropriate
c      number of new lines.
c
c      ip(1) = The applicable computer system number or 0 for all systems.
c      ip(2) = The file number:
c          1 = patchf
c          2 = makemcnp
c          3 = patchc
c      ip(3) = The applicable line number to edit-see the MCSETUP source.
c      ip(4) = The alter code:
c          1 = insert the following ip(5) line(s) before line ip(3)
c          2 = replace line ip(3) with the following ip(5) line(s)
c          3 = insert the following line after entry ip(5) of line ip(3)
c          4 = delete lines ip(3) through ip(5)
c      ip(5) = The number of new line(s) if ip(4)=1,2
c              The entry number if ip(4)=3
c              The last line number to delete if ip(4)=4
c
c      The number of new lines that follow ip(1)-ip(5) is given by:
c          = ip(5) if ip(4)=1,2
c          = 1 if ip(4)=3
c          = 0 if ip(4)=4
c
c***** FIXES FOR SYSTEM 1 (Cray UNICOS) *****
c

Patch to 4B with a few parallel enhancements:

```
c      <<<< makemcnp changes for MCNP4B2 >>>>      loddat 09/22/97
c
c  For each fix, enter five integer parameters on one line in free
c  format, ip(1)-ip(5) described below, followed by the appropriate
c  number of new lines.
c
c  ip(1) = The applicable computer system number or 0 for all systems.
c  ip(2) = The file number:
c    1 = patchf
c    2 = makemcnp
c    3 = patchc
c  ip(3) = The applicable line number to edit-see the MCSETUP source.
c  ip(4) = The alter code:
c    1 = insert the following ip(5) line(s) before line ip(3)
c    2 = replace line ip(3) with the following ip(5) line(s)
c    3 = insert the following line after entry ip(5) of line ip(3)
c    4 = delete lines ip(3) through ip(5)
c  ip(5) = The number of new line(s) if ip(4)=1,2
c          The entry number if ip(4)=3
c          The last line number to delete if ip(4)=4
c
c  The number of new lines that follow ip(1)-ip(5) is given by:
c    = ip(5) if ip(4)=1,2
c    = 1 if ip(4)=3
c    = 0 if ip(4)=4
c
